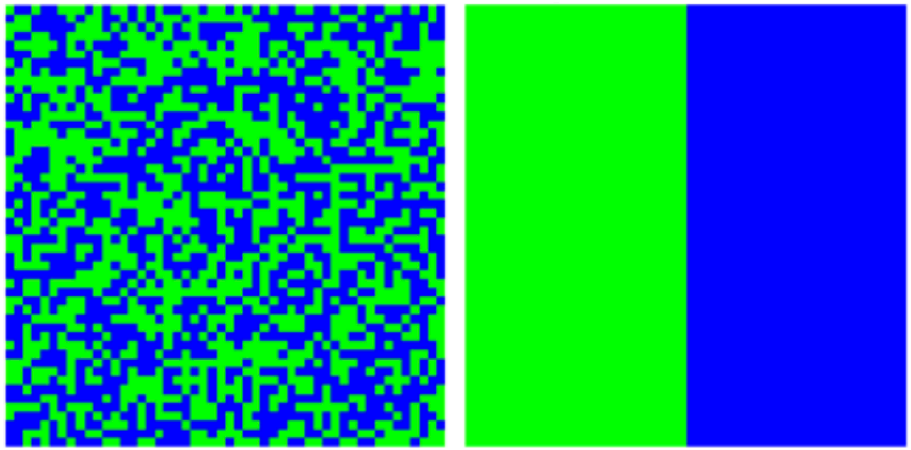
Spatial model of segregation

"Dynamic Models of Segregation", Thomas Schelling, 1971

- Micro-motives and macro-behavior
- Personal preferences lead to collective actions
- Global patterns of spatial segregation from homophily at a local level
- Segregated race, ethnicity, native language, income
- Cities are strongly racially segregated. Are people that racists?
- Agent based modeling: agents, rules (dynamics), aggregation

Segregation



Integrated pattern Segregated pattern

Racial segregation

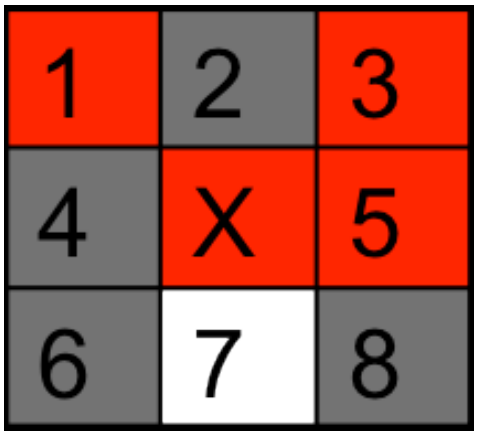
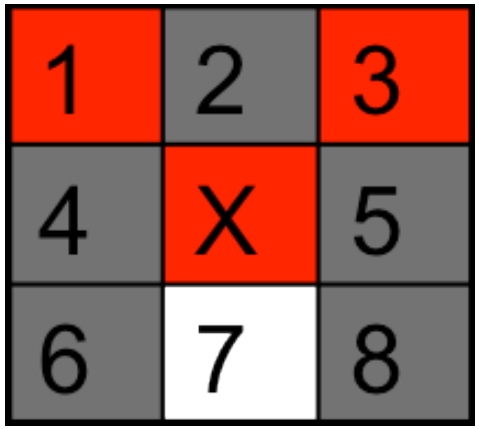
Schelling's model of segregation

- Population consists of 2 types of agents
- Agent reside in the cells of the grid (2-dimensional geography of a city), 8 neighbors
- Some cells contain agents, some unpopulated
- Every agent wants to have at least some fraction of agents (threshold) of his type as neighbor (satisfied agent)
- On every round every unsatisfied agent moves to a satisfactory empty cell.
- Continues until everyone is satisfied or can't move

Spatial segregation



satisfied agent



unsatisfied agent

- preference threshold $\lambda = 3/7$

Spatial segregation

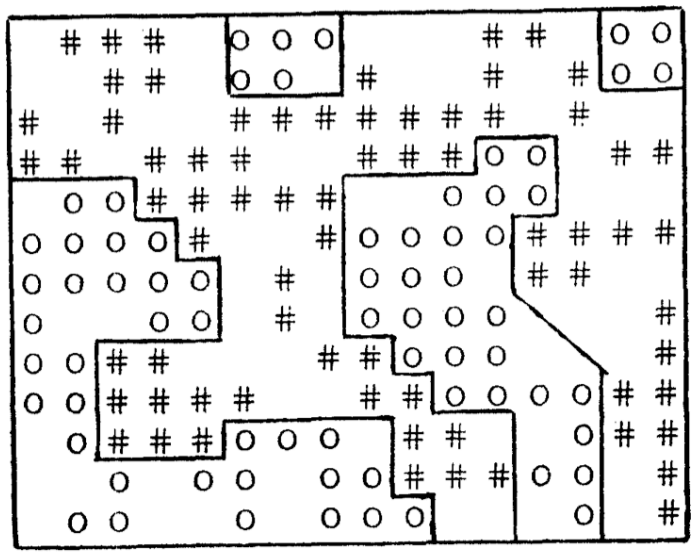

Fig. 10

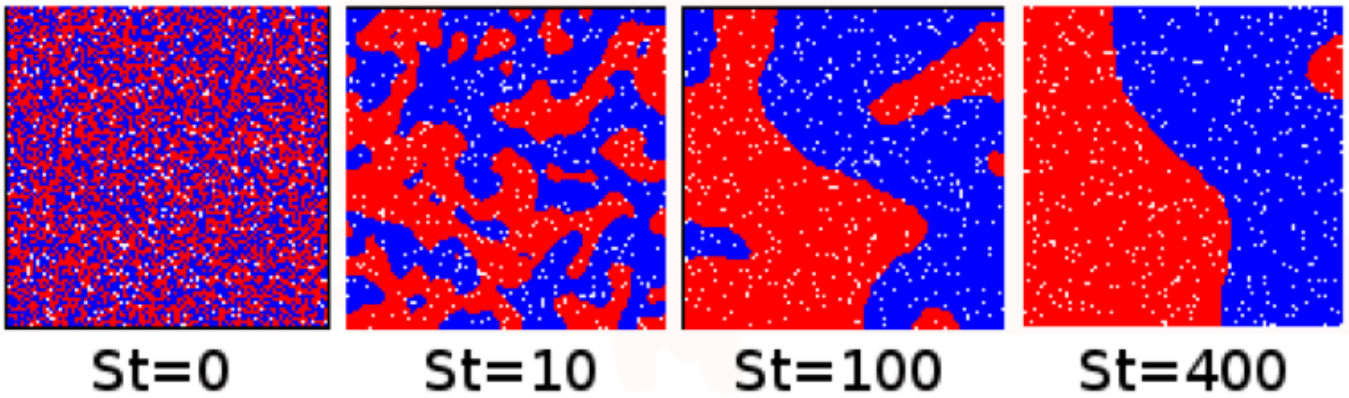
T. Schelling, 1971

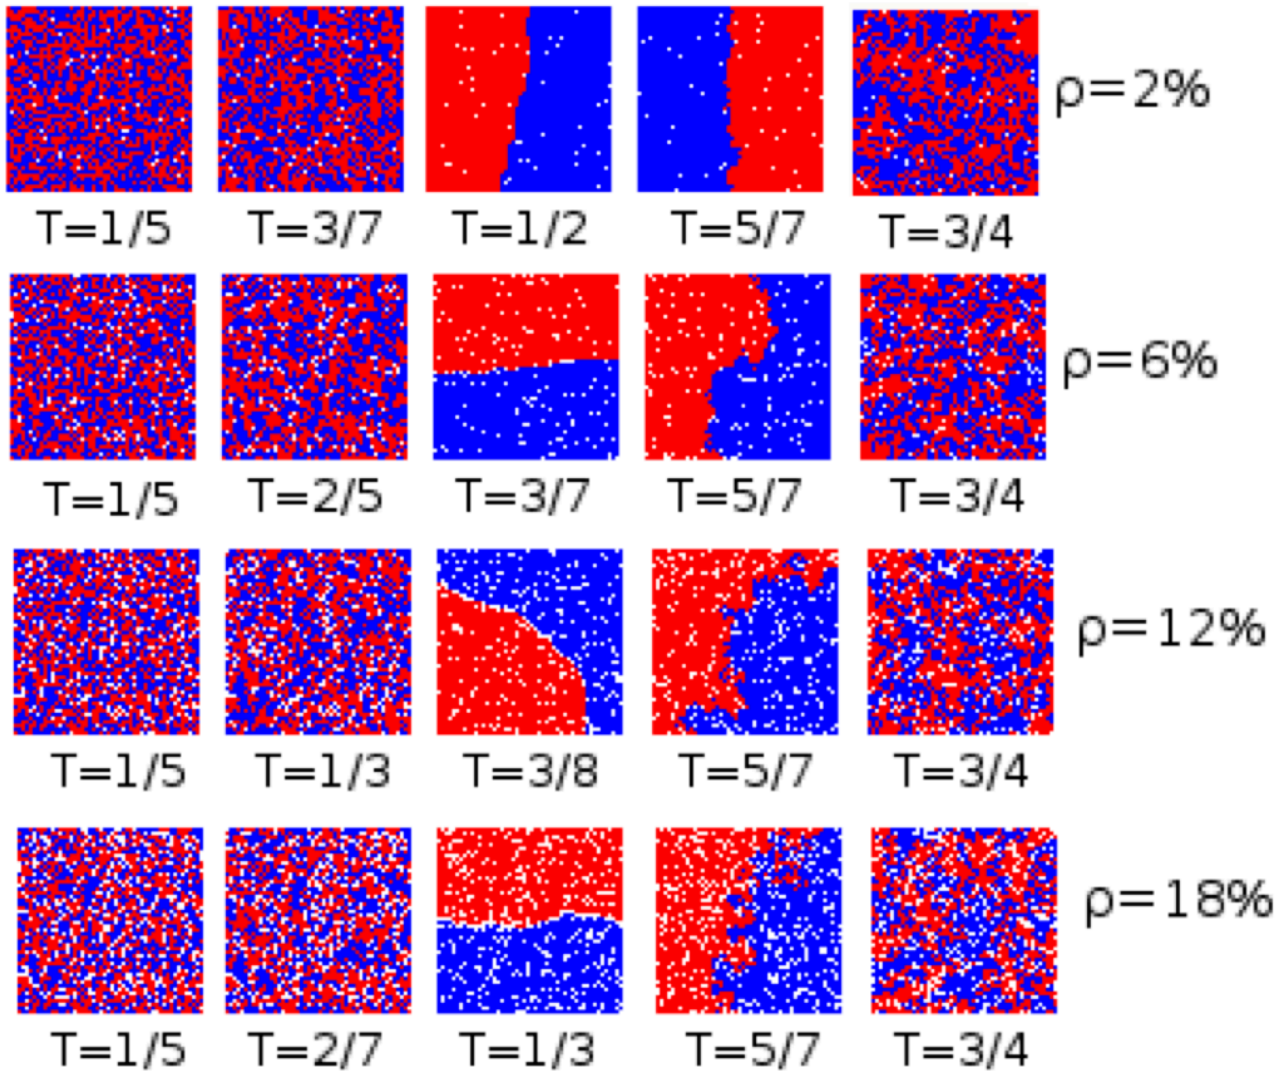
Spatial segregation

vacancy 5%, tolerance $\lambda = 0.5$



L. Gauvin et.al. 2009

Spatial segregation



Model

- N - nodes, θ - fraction of occupied by A and B

$$n_A + n_B = \theta \cdot N$$

- Proportion of "unlike" nearest neighbors, $k_i = \#NN$

$$P_i = \begin{cases} \#n_B/k_i, \text{ if } i \in A \\ \#n_A/k_i, \text{ if } i \in B \end{cases}$$

- Utility function, λ - sensitivity (tolerance threshold) level

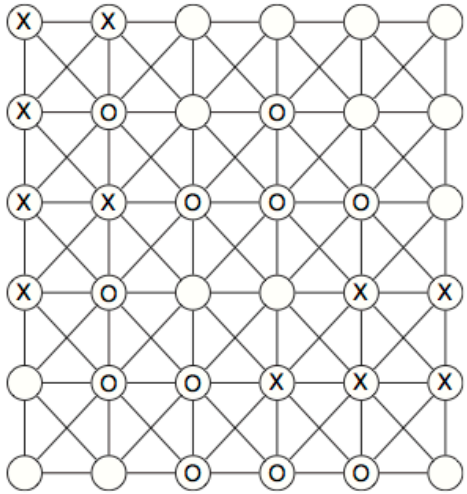
$$u_i = \begin{cases} 1, \text{ if } P_i \leq \lambda \\ 0, \text{ if } P_i > \lambda \end{cases}$$

- Every node moves to maximize its utility

Spatial segregation

x	x				
x	o		o		
x	x	o	o	o	
x	o			x	x
	o	o	x	x	x
		o	o	o	

(a)



(b)

Algorithm

- time steps $1..T$
- At every time step randomly select an agent, compute utility
- If utility is $u = 0$ move to an empty location to maximize utility
- Movements: 1) random location 2) nearest available location
- Repeat until either all utilities are maximized $\sum_i u_i = \theta N$ or reaches "frozen" state, no place to move, then $\sum_i u_i < \theta N$
- Total utility of society

$$U = \sum_i u_i$$

Measuring segregation

- Schilling's solid mixing index

$$M = \frac{1}{n_A + n_B} \sum_i P_i$$

- Freeman's segregation index

$$F = 1 - \frac{e^*}{E(e^*)}$$

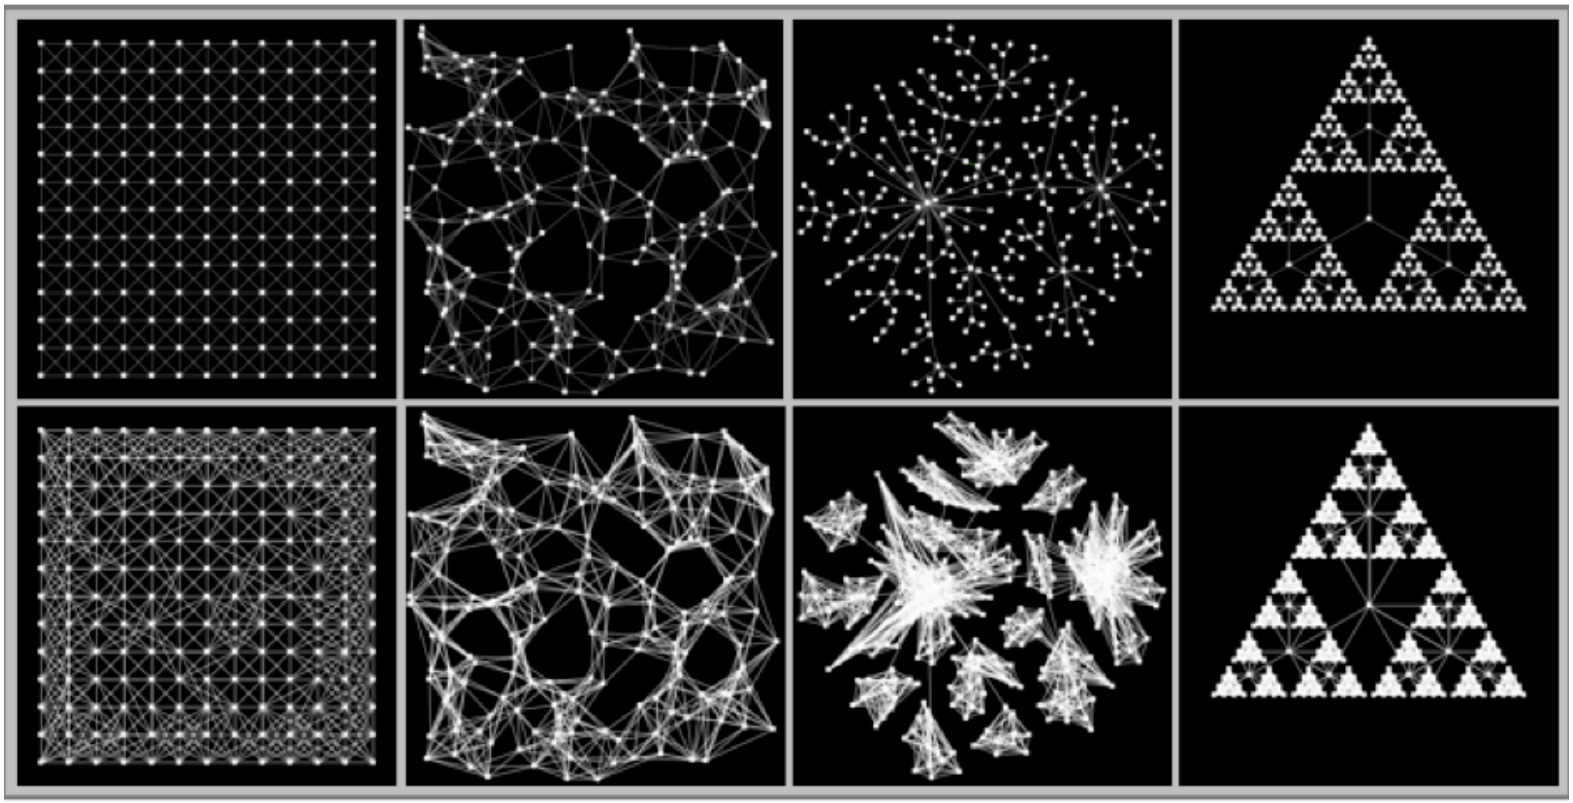
$e^* = \frac{e_{AB}}{(e_{AB}+e_{AA}+e_{BB})}$ - observed proportion of between group ties,
$E(e^*) = \frac{2n_A n_B}{(n_A+n_B)(n_A+n_B-1)}$ - expected proportion for random ties

- Assortative mixing

$$Q = \frac{1}{2m} \sum_{ij} (A_{ij} - \frac{k_i k_j}{2m}) \delta(c_i, c_j)$$

Spatial segregation on networks

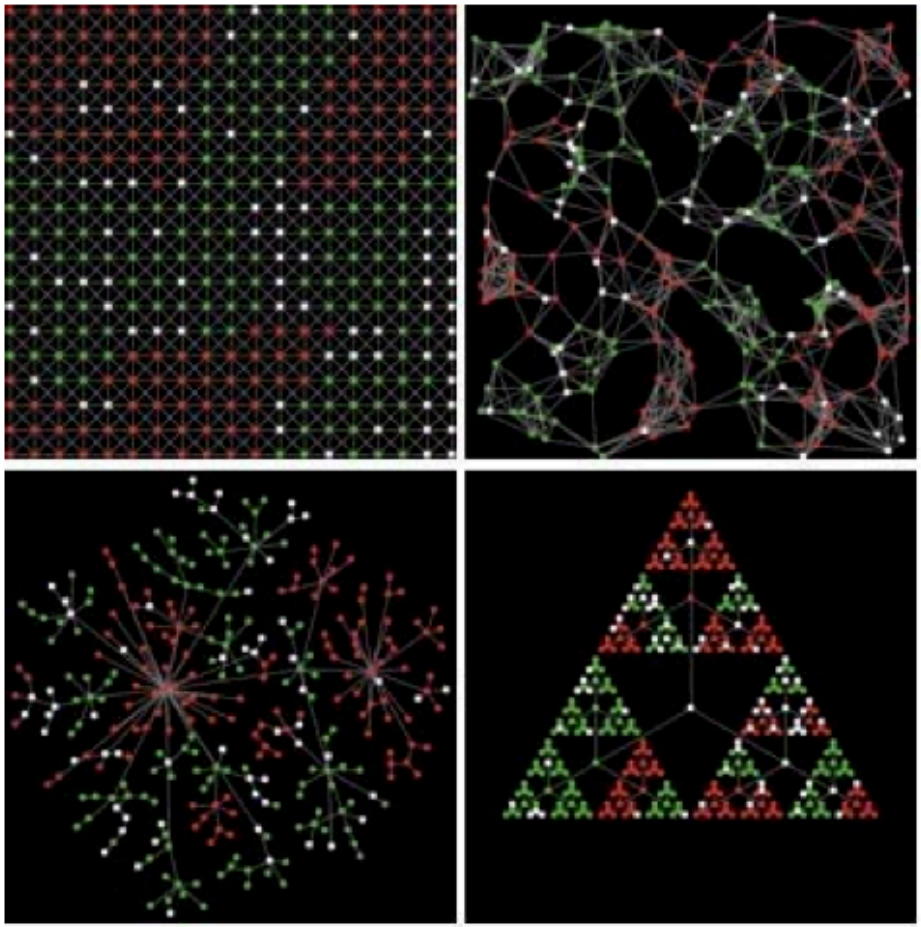
Fixed degree $k = 10$ neighboring graphs: regular, random, scale-free, fractal



Arnaud Banos, 2010

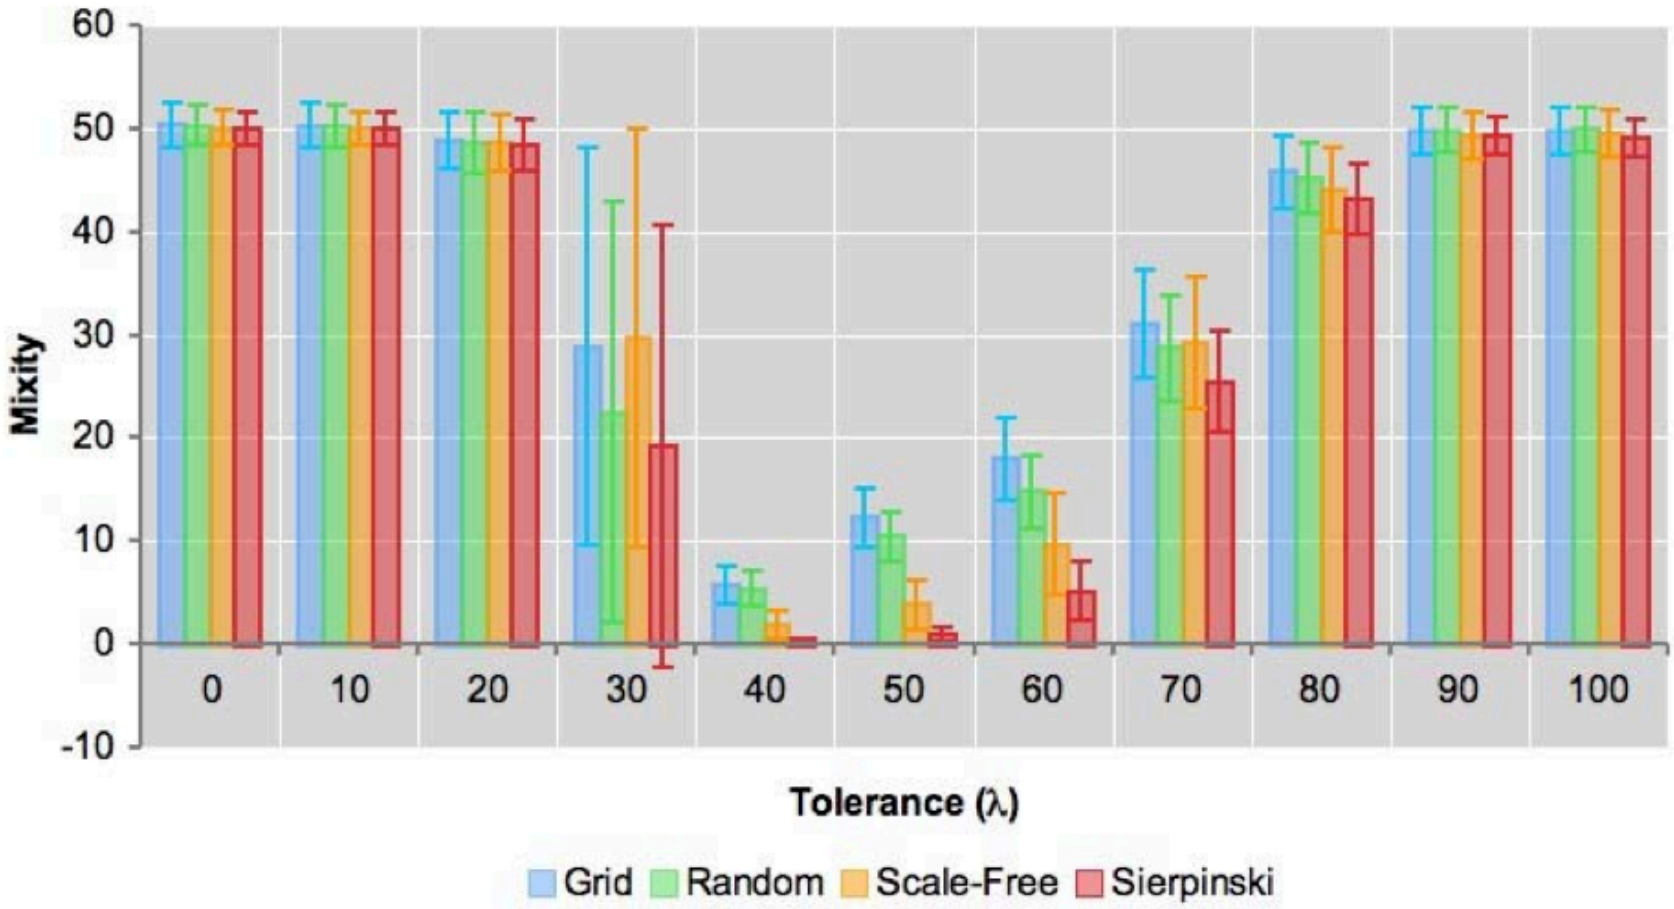
Spatial segregation on networks

$\lambda = 0.5, \theta = 0.8$



Banos, 2010

Spatial segregation on networks



Banos, 2010

Summary

- Spatial segregation is taking place even though no individual agent is actively seeking it (minor preferences, high tolerance)
- Network structure does affect segregation
- Fixed characteristics (race) can become correlated with mutable (location)

Course summary

1. Introduction to network science
2. Descriptive network analysis
3. Mathematical models of networks
4. Node centrality and ranking on networks
5. Network communities
6. Epidemics and information spread
7. Diffusion of innovation
8. Spatial model of segregation
